#### Abstract

A major concern among many European policy makers in recent years has been the perception that a sizeable proportion of couples in low-fertility countries fail to realise their desired fertility. In this study, based on data from the 2011 Eurobarometer on Fertility and Social Climate, I examine different family size preferences and their link with actual fertility with the aim to see whether there is a correspondence between the number of children Europeans would like to have and the number they are actually having. The data reveal that around $30 \%$ of women and men end their reproductive career with fewer children than they previously considered ideal and that the difference between their mean ideal and actual family size is around 0.3 children. This measure can be higher in some countries, like Italy, and in some social groups, like highly educated persons. The preference for a two-child family is still pervasive in Europe and it has even been growing in the EU-15 countries over the decade 20012011. This result holds true for Greece and Portugal as well, the two countries which showed a clear decline in their mean family size ideals over the past 5 -year period (2006-2011). Social climate is rather negative in Europe. The most optimistic people about both their own life and their country's socio-economic situation are, on the one hand, childless persons and, on the other, those who have or would like to have large families with three or more children. This result, which contains an intrinsic contradiction, needs to be studied more thoroughly in further research.

[^0]
## INTRODUCTION

A major concern among many European policy makers in recent years has been the perception that a sizeable proportion of couples in lowfertility countries fail to realise their desired fertility. Indeed in low-fertility contexts modern contraception methods make it easy for people and couples not to have any children while people who do want to have children may face a series of constraints which impede them from reaching their goals. As a consequence, people usually end their reproductive career with fewer children than they would have liked to have had.

In this study, based on data from the 2011 Eurobarometer, different family sizes are examined with the aim to see whether there is a correspondence between the number of children Europeans would like to have and the number they are actually having. The analysis is carried out at the aggregate level, by looking at the EU-27 as a whole, as well as in a crosscountry perspective, by highlighting the differences across countries. While the main emphasis is on the most recent EB data (2011), the trend in the mean ideal family size over the past decade (2001-2011) is also examined. The aggregate analysis of the temporal changes is conducted separately for the first 15 European Member States and the 12 New Member States of the European Union because for the latter group data are available only for the period 2006-2011.

The Eurobarometer surveys are designed for comparative analysis among national populations. Stratified sampling assured nearly equal probability samples of about 1,000 respondents in each of the nations (with the exception of: Cyprus, Malta, Luxembourg and eastern Germany for which the sample size is 500 ). The national sample sizes are rather small but allow equally precise estimates for small and large countries, as well
as some comparisons between sub-groups broken down by sex, age, and educational attainment. The surveys use a single uniform questionnaire design, with particular attention being paid to equivalent question wording across languages. Question wording is of great importance in measuring fertility intentions, as responses depend significantly on how the questions are phrased, with even small differences in wording leading to considerable differences in stated intentions. The comparability of the results across nations is also enhanced by the use of a single multilingual survey collection team. Moreover, the questions on ideal and actual family size asked in 2011 used exactly the same wording as the previous rounds (2001 and 2006) which allows for comparisons through time of each of the childbearing measures.

I focus on four broad age groups: 1524 years, which includes people born between 1987 and 1996, 25-39 years, which refers to the cohorts born between 1972 and 1986, 4054 years, which encompasses people born between 1957 and 1971, and 55 or above, which includes men and women born in 1956 or earlier. It is worth noting that the age differences may roughly approximate but do not correspond to those of the same individuals observed over different stages of life. While framing the results in a cross-sectional perspective, it should be kept in mind that reproductive ideals and intentions, as well as actual fertility, are developmental by nature and change over the individual's life course. As well known in the literature, the adjustments of the fertility goals over the life course tend to occur mainly downward in response to different factors and events, one of which is of particular importance, i.e., the transition to a first or a higher birth order child.

The analysis is organised in short sections which are aimed at describing specific aspects related to the ideal, intended and actual family size, as well as to the level of correspondence between them. The last two sections are reserved for the study of social climate in Europe and its link to actual and ideal fertility. Individuals' satisfaction with their own life and individuals' evaluation of their country's socio-economic situation are also investigated in relation with both their ideal and their actual family size. Although the sections are connected to each other, each of them can be read and understood independently and contains ideas for further close examination.

The investigation presented in the main text is supplemented by material provided in two Appendixes. The first one contains several figures and tables that are commented on in the main text but could not be included without interrupting the reading flow. The second one includes several tables with the mean values and the full distribution of the ideal, intended and actual family size by gender, age and country. These tables should facilitate and deepen the understanding of the figures and tables reported in the main text.

This analysis of the 2011 EB findings on childbearing preferences and family size in Europe is by no means exhaustive but only aimed at outlining some of the main results and pointing out the most interesting areas for further in-depth research.

## 1. DEFINITIONS OF FAMILY SIZES AND SURVEY ITEMS

The questions on childbearing included in the 2011 round of the Eurobarometer survey are reported in Table 1. Most of them are asked in exactly the same way during the previous two rounds (2001 and 2006), which allows for comparisons through time.

General ideal family size reflects childbearing preferences at the normative level, i.e., the societal ideal or norm. Personal ideal family size reflects childbearing preferences at the individual level but in absence of any possible obstacle, that is, under ideal conditions. The concept is close to that of desired family size which expresses wishes and emotional feelings without containing any commitment to act. These two concepts or measures supply complementary information about fertility decision-making: while a society's ideal refers to the society as a whole, a personal ideal is an expression of one person's fertility desires. The two survey items offer several numerical answers ranging from zero to more than six, and also explicitly consider the two options 'there is no number' and 'don't know' (Table 2). In this study more emphasis is given to the personal ideal family size, considered to be the most direct measure
of the respondent's own attitudes (Goldstein et al. 2003).
Actual family size reflects the number of children already born. In the Eurobarometer survey the construct refers only to biological children and does not consider any adopted or step-children. The survey item offers a series of response options ranging from 'zero' to 'more than six' children and provides also the option 'don't know' (Table 2).

Additionally intended family size reflects the number of children individuals plan to have over the entire reproductive span (also known in the literature as lifetime fertility intentions). The survey item offers a series of numerical answers ranging from 'zero' to 'more than ten' children and provides also the option 'don't know' (Table 2). Unlike the ideals, which are linked to more enduring individual's characteristics and genetic endowments, this construct takes into account the various external and internal constraints (of different nature) that people may face when trying to achieve their fertility goals. In the demographic literature lifetime fertility intentions are considered as goal-related actions, the most proximate determinants of childbearing behaviour.

Table 1 Wording of the questions on family size. Eurobarometer survey 2011.

| Order | Family sizes | Survey items: |
| :--- | :--- | :--- |
| 1 | General ideal | Generally speaking, what do you think is the ideal number of <br> children for a family? |
| 2 | Personal ideal | And for you personally, what would be the ideal number of <br> children you would like to have or would have liked to have <br> had? |
| 3 | Actual | How many children, if any, have you had? |
| 4 | Additionally intended | How many (more) children do you intend to have? |

[^1]Table 2 Response options to the different family size items

|  | Family sizes |  |  |
| :--- | :---: | :---: | :---: |
| Response Options | Ideal | Actual | Intended |
| None | $\times$ | $\times$ | $\times$ |
| One | $\times$ | $\times$ | $\times$ |
| Two | $\times$ | $\times$ | $\times$ |
| Three | $\times$ | $\times$ | $\times$ |
| Four | $\times$ | $\times$ | $\times$ |
| Five | $\times$ | $\times$ | $\times$ |
| Six | $\times$ | $\times$ | $\times$ |
| Seven (or more) | $\times$ | $\times$ | $\times$ |
| Eight |  | $\times$ |  |
| Nine |  | $\times$ |  |
| Ten or more | $\times$ | $\times$ |  |
| No ideal | $\times$ | $\times$ | $\times$ |
| Don't know |  |  |  |

Note: Ideal family size refers to both general and personal ideal. The option 'no ideal' provided in the items on general and personal ideal family size corresponds to the following answer "there is no number, it depends". This option was offered also in the 2006 EB round where it was phrased as follows: "There is no ideal number, it depends".

Ultimately intended family size is a construct computed by summing up the actual and the additionally intended number of children. Because of the developmental nature of both components, actual and additionally intended family size, the ultimately intended family size takes a different composition at different ages: at the beginning of the reproductive span it reflects mainly the intended family size; at the end of the reproductive span it reflects mainly the actual family size. One could expect to see a progressive narrowing of the difference between ultimately intended and actual family size until the end of the reproductive span not only because of people's transitions to higher parities but also because of people's (reiterated) adjustments of lifetime fertility intentions due to internal and external constraints and competing preferences. At the
end of the reproductive span, given that no one can intend to have fewer children than they already have, ultimately intended family size completely overlaps actual family size. For the purpose of guiding public policy, this construct is most useful as an estimate of the final parity.

Family size ideals are relatively stable over the individuals' life, being influenced by enduring motivational traits and genetic factors. By contrast, actual family size increases and intended family size decreases over the childbearing ages as people progress to higher parities.

The difference between ideal and actual family size, termed ideal-actual gap, gives us an approximation of how much reproductive wishes have been realised. The difference between ideal and intended family size, so called ideal-intended gap, reflects the extent to which individuals have modified their family size intentions away from their desires as a result of constraints and competing activities. This kind of gap might indicate the problem areas at which social policy should be directed to help individuals realise the family size they intrinsically desire. The difference between ultimately intended and actual family size, intended-actual gap, is just the number of additional children individuals plan to have for the future. By definition, it tends to be null at (near) the end of the individuals' childbearing years.

In the reproductive ages, 15-24 and 2539 , when people do not have yet a complete family size, the ideal-actual gap is examined by looking separately at its two components, namely the ideal-intended and the intendedactual gap. At ages 40 and above only the ideal-actual gap is relevant.

For a more detailed discussion of measurement and definition issues, see Morgan et al. 2011.

## 2. GENERAL AND PERSONAL IDEAL FAMILY SIZE: ARE THERE DIFFERENCES?

In 2001 a distinction between general and ideal family size was introduced in the EB questionnaire. Respondents were asked to report not only their ideal number of children for a family in general, but also the ideal number of children that they themselves would like to have, or would have liked to have had. Note that the question on personal ideals, unlike the one on general ideals, contains two different expressions for those who are in the reproductive ages ('would like to have') and those who are no longer in the reproductive ages or have stopped childbearing ('would have liked to have had'). The item takes a prospective or a retrospective connotation depending on whether individuals are still able (or plan) to have children or not. This circumstance might have pushed individuals to think about their personal ideals as being more closely related to their own reproduction than their general ideals. Figure 1 supports this interpretation in part, showing that the mean personal ideal family size is higher than the mean general ideal family size at parity three or above.

Figure 1 Mean general and ideal family size by actual number of children. EU-27

Since the wording of the two questions is quite similar, the extent to which respondents might have understood the
difference between general and personal ideal family size is unknown.

At the EU-27 level, the mean general and personal ideal family sizes are very close to each other, the absolute difference range from 0.02 to 0.14 . Furthermore, there is a high cross-country correlation between them (0.9). Two out of three respondents report the same answer to the two items (on average 2.1 children) and the other one third is equally subdivided between those having personal ideals higher than general ideals and those for whom the opposite is true. If general and ideal family sizes are discrepant, personal ideals tend to be higher than general ideals among women and persons aged 40 or above, while for men and young people it is the other way around (Figure 2).

Figure 2 Mean general and mean personal ideal family size among respondents reporting different answers to the two items. EU-27

## 3. THE PREFERENCE FOR A TWO-CHILD FAMILY

The preference for a two child-family is still pervasive in Europe (Figure 3). This is the most frequently reported answer not only for the general but also for the personal ideal family size, selected by more than $50 \%$ of the respondents. The second most frequent answer is 'three or more children' reported by $22 \%$ and $26 \%$ of interviewed people as a general or personal ideal, respectively. The third most frequent answer is 'one child': $7 \%$ and $9 \%$ of respondents choose this option for their general and personal ideal family size, respectively. Moreover, $10 \%$ of respondents say that there is no number for the general ideal and 5\% declare that there is no number of the personal ideal.

The distribution of respondents by their own ultimately intended family size is less concentrated around the two-child option, with $41 \%$ of people indicating this as an answer. Moreover, a non-marginal proportion of women and men report 'no child' intended
$(9 \%)$ or is 'unsure' about the number of children intended (11\%). The share of those reporting a no child preference or who are undecided are much lower in the items on general ideal family size, $2 \%$, and personal ideal family size, $4 \%$.

The distribution of interviewed people by actual number of children is different from those of ideal or ultimately intended family size. First, the same share of people report to have 'two children' and 'no child', $32 \%$; second, large families (three or more children) are as frequent as small families (only one child), $18 \%$ of the respondents. In this context one should note that the sample includes a relatively high proportion of young people who have not yet started a family.

The preference for a two-child family has been growing in the $15-\mathrm{EU}$ countries over the last decade (Figure 4).

Figure 3 Distribution of Europeans by different family sizes. EU-27

One can observe a raise in the concentration of people reporting two children as their general or personal ideal family size over the decade 2001-2011: from $52 \%$ to $57 \%$ for the general ideal and from $49 \%$ to $52 \%$ for the personal ideal (Figure 4, first and second graph), a stability in the preference for small families (less than two children), and a decrease in the preference for large families (three or more children) from $26 \%$ to $22 \%$ for the general ideal and from $30 \%$ to $27 \%$ for the personal ideal.

The share of people reporting two children as their own actual family size also increases from $29 \%$ to $32 \%$ (Figure 4, third graph), while temporal changes in the
ultimately intended family size are characterised by a slight decline in the option for large families, from $27 \%$ in 2001 to $25 \%$ in 2011, and a boost of uncertainty about reproductive plans, from $7 \%$ in 2006 to $10 \%$ in 2011 (Figure 4, fourth graph).

In the $12-\mathrm{NMS}$ the temporal changes over the five-year period 2006-2011 are characterised by a substantial stability in the two-child norm and a slight increase in the share of people who have a family with exactly two children at the time of the survey (Figure A.1.8). Uncertainty about fertility plans almost doubles from $6 \%$ to $10 \%$ in the 5 -year period 2006-2011.

Figure 4 Ideal, ultimately intended and actual family size over the period 2001-2011. EU-15

## 4. PERSONAL IDEAL, ULTIMATELY INTENDED AND ACTUAL FAMILY SIZES: PATTERNS BY AGE AND GENDER

The mean personal ideal family size increases with age in the EU-27 as a whole. Considering the changes from the youngest to the oldest ages, the mean values go from 2.1 to 2.4 children among women and from 2.0 to 2.3 children among men. Women's ideals are higher than men's ideals in each age group (Figure 5).

As expected, the mean actual number of children shows a rising path with age: values go from 0.2 to 2.2 children among women and from 0.1 to 2.2 children among men (Figure 5). Here, again, women's mean actual number of children is higher than men's one for each age group.

The mean ultimately intended number of children is above two children for women and at around two children for men in all but ages $40-54$ (Figure 3). This measure is very close (only slightly lower than) to the mean ideal family size at ages 15-24 and tends to overlap the values of the mean actual family size at ages $40-54$ among women but not
among men who still intend to have children at these ages. At ages 55 or above, people have usually completed their family. Hence, their ultimately intended coincides with their actual family size.

At ages 15-24, the difference between the mean ideal and the mean actual family size takes its maximum value of about two children, while the difference between mean ideal and mean intended family size is only marginal. At age 55 or above, the ideal-actual gap corresponds to the ideal-intended gap which is equal to 0.3 and 0.2 children for women and men, respectively (Figure 5). This suggests that European women and men would have liked to have had, respectively, 0.3 and 0.2 children more than those they have actually had by the end of their reproductive career.

This measure might be, however, an underestimation of the children that Europeans have definitively given up, as will be explained in the next section.

Figure 5 Mean family sizes by gender and age. EU-27

Typically, the same age pattern observed at the EU-27 level is replicated in each of the 27-EU countries, for both women and men (Figure A.1.1). The mean ideal family size is at around or above two children in most of the countries. Exceptions are provided, on one hand, by Austria, which shows belowreplacement ideals in each age group up to the ages $40-54$ and, on the other hand, by Ireland and Cyprus, where the rising path of ideal size with age is particularly steep and ends with values of three or more children at age 55 or above (Figure 6 and Figure A.1.1).

The mean actual family size goes from no child at ages 15-24 to 2 children or more at ages 55 or above. Values clearly above 2 are observed in Ireland (3.7 and 3.2 for women and men, respectively) and Cyprus (slightly less than 3 for both women and men). The mean actual family size tends to converge with the values of the mean ideal family size without completely overlapping them, even at the oldest ages, in most of the countries (see, for example, Estonia and Greece in Figure 6).

The age pattern of the mean ultimately intended family size varies from country to country: it is quite stable in Bulgaria, Belgium (men) Czech Republic, Finland (men), France, Italy (men), Luxembourg (women), the United Kingdom and Romania (men); it takes a Ushape in Austria, Denmark, Germany (men), Greece (men), Italy (women), Portugal, Slovakia (women) and Spain; it decreases in Estonia, Latvia, Lithuania, the Netherlands (women) and Slovenia; it increases in Cyprus, Malta and Ireland. Generally, the mean ultimately intended family size is equal or slightly lower than the mean ideal family size at ages 15-24 and 25-39 and is very close to the mean actual family size at ages $40-54$. In France and Hungary the mean ultimately intended family size is higher than the mean ideal family size at these ages (Figure A.1.1).

In three countries, the Czech Republic, Malta and the United Kingdom, the values of the mean ideal and mean ultimately intended family sizes overlap each other for both women and men in each age group (Figure A.1.1).

Figure 6 Mean ideal, ultimately intended and actual family size. Several EU countries.

## 5. Changes in the distribution of ideal family size across ages

The difference between the mean ideal and mean actual family size observed at age 55 or above may not truly reflect the real number of children missed by Europeans because individuals might have adjusted their ideals in order to match them with their own actual family size.

One can get an idea of this readjustment process by comparing the distribution of childless people and parents by the ideal family size in different age groups (Figure 7). Little changes of ideal family size are observed across ages in the parents subsample. The preference for a two-child family is reported by almost $60 \%$ of parents at each age. Considering the changes between the youngest and the oldest people, the percentage of those preferring smaller families decreases from $14 \%$ to $8 \%$ and the share of those preferring larger families slightly increases from $32 \%$ to $34 \%$. By contrast, the distribution of childless people by ideal family size clearly changes with age. The preference for small families (less than two children) doubles from $14 \%$ at ages $15-24$ to $28 \%$ at ages $55+$, and the
preference for large families (more than two children) is cut in half from $26 \%$ at ages 15-24 to $13 \%$ at ages $40-54$. These different age patterns in each of the sub-samples might provide a sign for a downward adjustment of ideal to the actual fertility, although they do not prove that these people have revised their family size ideals through their lives. Importantly, an analogous change in the distribution of people by ideal family size across age is not observed if the whole sample is stratified between those who have large families (three or more children) and those who have up to two children. Almost $20 \%$ of people in this latter group and $80 \%$ of people with large families indicate three or more children as an ideal family size at each age (results are not shown but can be provided upon request).

This finding supports the evidence found in several longitudinal studies (Liefbroer 2009) that downward adjustments of childbearing ideals occur more frequently than upward adjustments.

Figure 7 Distribution of Europeans by ideal family size in different age groups. EU-27

## 6. THE CORRESPONDENCE BETWEEN IDEAL AND ACTUAL FAMILY SIZE

In Figure 8 the difference between the mean ideal and the mean actual family size is reported for different age groups in several years. As expected, the size of the ideal-actual gap decreases with age as people progress to higher parities. The difference goes from around two children at ages $15-24$ to 0.25 children at ages 55+. In the prime reproductive ages the difference is slightly below (women) or above (men) 1 child. For younger people (age groups 15-24 and 25-39), the discrepancy between ideal and actual family size is particularly high because people still have to get (some or all of) the children they would
like to have. At these ages only a measure of temporary discrepancy between actual and desired fertility can be computed. The size of this measure is strongly influenced by the timing of childbearing, and especially by the moment at which people start their family.

A slight increase of the difference between ideal and actual family size is registered over the period 2001-2011. The increase concerns women and men of all ages in the EU- 15 and only women aged 40 or above and men aged $25-54$ in the $12-\mathrm{NMS}$ (Figure 8).

Figure 8 Difference between the mean ideal and the mean actual family size by age and gender.

There is broad cross-country variation in the correspondence between the mean ideal and the mean actual family size. In Figure 9 the mean ideal family size of women aged 2539 by country is reported. The mean ideals are decomposed into the mean actual number of children, the mean additionally intended number of children, and the mean children of children needed to reach the family size that people ideally would like to have. Countries are ordered according to the final estimated parity, i.e., actual plus intended number of children. Labels are shown only for these two variables while, for the sake of simplicity, the

figures related to the number of children needed to reach the family size ideals beyond those additionally planned for the future are not shown.

As we can see, in the EU-27 as a whole, women aged 25-39 have on average 1.2 children and plan to have, on average, 0.8 or more children. Hence, the completed family size estimated for these female cohorts born between 1972 and 1986 is exactly two children. If they would manage to have all the children they plan to have, which is an unrealistic assumption (Testa and Philipov 2011), about 0.1 children would still be needed
to reach their ideal family size. These values range from 0 (the United Kingdom and the Czech Republic) to 0.5 children (Cyprus) across the EU-27 countries (Figure 9). In Hungary, France and Ireland the number of children needed to reach the family size ideals is negative: Hungary ( -0.3 ), France ( -0.1 ) and Ireland ( -0.1 ). For the sake of simplicity, these negative values are not shown in Figure 9. In the Appendix results for men aged 25-39 are also reported. (Figure A.1.2). The rank of the countries by the estimated completed family size is similar to that observed for the women:

Austria and eastern Germany are at the bottom and France and Ireland at the top of it. For women aged 40-54, the size of the ideal-actual gap is 0.4 for the EU-27 as a whole and it ranges from 0.1 (Malta) to 0.6 (Denmark and Italy) and 0.8 (Sweden) across the EU countries (Figure 9). The values for men of the same age category are slightly higher: 0.5 for the EU-27 as a whole and the range across countries goes from 0.1 (eastern Germany) to 1 child (Greece) (Figure A.1.3)

Figure 9 Mean ideal family size obtained by summing up different components of family sizes. EU-27

[^2]- actual number of children
- number of children needed to reach the ideals

## 7. GENDER DIFFERENCES IN FAMILY SIZE IDEALS

Women's mean personal ideal family size exceeds the ideals of men in most of the EU countries. If one considers all age groups, only seven out of 27 countries show men's mean ideal family sizes higher than women ones and the differences are rather small ranging from 0.1 (Romania) to 0.02 (Spain and Portugal). By contrast, the women's ideals are up to 0.4 children higher than those of the men (Figure 10).

Since men start a family later in life than women, women do also have larger actual family size than men at each age (Figure A.1.1). Hence, one could have expected to see the same degree of difference between ideal and actual family size among women and men.

Figure 10 Mean personal ideal family size by gender. All ages

By contrast, the difference between ideal and actual family size is larger among men than among women (figure 11). Women differences are below 0.5 children, with the exception of Sweden, Finland and Denmark. Men's differences are at 0.5 or above with the exception of Bulgaria, the Czech Republic, Portugal, Germany Hungary, Slovakia, Belgium, Luxembourg, the Netherlands and the United Kingdom.

A reversal of these gender differences is observed at ages 40-54 for Finland, Sweden, Denmark, the Netherlands, Luxembourg, Hungary, the Czech Republic, and eastern Germany (Figure 11).

Figure 11 Difference between mean ideal and mean actual family size by gender. Ages 40-54

## 8. HOW MANY EUROPEANS REALISE THEIR FAMILY SIZE IDEALS?

The correspondence between mean ideal and mean actual family size does not inform us about the share of people that has realised their reproductive wishes.

To know the prevalence of those who realise their reproductive wishes one can look at the distributions of women and men by different combinations of ideal and actual family size (Figure 12). The distributions are given for each age group as well as for the total. In each of these categories the sum of the proportion by different combinations of ideal and actual family size should sum up 100 .

Overall, almost half of the Europeans declare to have an actual family size equal to the ideal one, $49 \%$ of women and $45 \%$ of men. A similar share of people, $44 \%$ of women and $49 \%$ of men, show an ideal family size greater than an actual family size and only a tiny
minority, $7 \%$ of women and $6 \%$ of men, have ideal family sizes smaller than actual family sizes (Figure 12).
This pattern changes across ages. At ages 1524 almost all the respondents have an ideal higher than an actual family size, about $90 \%$; at ages 25-39, around two out of three respondents show the same gap; at ages 40-54, the share is around one out of three respondents and at age 55 or above it is one out of four, for both women and men. The share of women and men with their ideal equal to their actual family sizes increases from $10 \%$ at ages $15-24$ to around $60 \%$ at ages 55 or above. The percentage of those who have an ideal smaller than their actual family size slightly goes up to $10 \%$ in the oldest ages (Figure 12).

Figure 12 Distribution of Europeans by different combinations of ideal and actual family size. EU-27

There is an increase over time (20012011) in the share of people who harbour ideals greater than their actual family size in the EU-15 (Figure 13). Such a time trend is observed for men aged 25-39 and 40-54 and for all women irrespective of their age.

Similarly, in the 12 NMS the proportion of women and men with fewer children than those considered ideal increases in the central ages, 25-39 and 40-54, and decreases in the extreme ages 15-24 and 55+ between 2006 and 2011 (Figure 14).

Figure 13 Proportion of women and men who have fewer children that those considered ideal by gender and age. EU-15

Figure 14 Proportion of women and men who have fewer children than those considered ideal by gender and age. 12-NMS

As more and more women and men postpone childbearing to older ages in life, one could have expected a temporal increase in the share of women and men who have fewer children than those considered ideal in the prime reproductive ages, 25-39. An increase over time of those with fewer children than those considered ideal, however, is observed also among women and men aged 40-54 who have presumably completed their reproductive career. This suggests that the temporal trend described in Figures 13 and 14 is not only due
to the increasing postponement of childbearing.

There is broad cross-country variation in the share of people who end their reproductive career with fewer children than those considered ideal. The percentages range from 20\% (Malta and Czech Republic) to $61 \%$ (Greece) for men (Figure 15) and from 18\% (Bulgaria) to $45 \%$ (Denmark) for women (Figure A.1.5).

Figure 15 Distribution of men aged 40-54 by different combinations of ideal and actual family size

## 9. THE CONTRIBUTION OF CHILDLESSNESS TO THE (LACK OF) CORRESPONDENCE BETWEEN IDEAL

 AND ACTUAL FAMILY SIZEFigure 16 looks at the size of the difference between the mean ideal and the mean actual family size by age among childless people and parents separately. The difference goes from 0.7 children at ages $15-24$ to 0.2 at ages 40-54 and almost disappears at age 55 or above among parents. By contrast, it decreases only from 2.2 to 1.5 and 1.8 in the childless group. Given that in the two first age groups, 15-24 and $25-39$, there is a high proportion of people who are childless, $89 \%$ and $46 \%$, respectively, temporary childlessness makes a significant contribution to the ideal-actual gap in the reproductive ages. At ages $40-54$ and 55 or above the share of childlessness is only $17 \%$ and $10 \%$, respectively. Hence, definitely childlessness is not contributing much to the ultimate size of the gap. Importantly, the mean ideal family size is relatively high, 1.5 and 1.8 children, for childless people aged 40-54 and 55 or above, respectively, suggesting that a family with children is still considered an ideal by many of them.

Figure 16 Difference between the mean ideal and the mean actual family size by age. EU-27

There is a high and statistically significant cross-country correlation ( $\mathrm{r}=0.51$ ) between the share of women and men with actual families smaller than the ideal ones and
the share of childless women and men at ages 25-39, signalling that temporary childlessness due to childbearing postponement might be an important contributing factor to the share of the ideal-actual gap at these ages. By contrast, at ages 40 and above the correlation decreases substantially $\quad(\mathrm{r}=0.19)$, suggesting that definitive childlessness is not the major explanation for the ultimate discrepancy between ideal and actual family size (Figure 17 and Figure A.1.10).

Figure 17 Cross-country relationship between childlessness and the share of people with fewer children than those considered ideal

B) Ages 40 and above

## 10. BELOW-REPLACEMENT FAMILY SIZE IDEALS IN AUSTRIA

Below-replacement family size ideals were observed in Austria for the first time in 2001 (Goldstein et al. 2003). They have been stable over the period 2001-2011 (Figure 18), suggesting that small families with less than two children have become the norm in this country (Testa 2012). The 2011 EB data, however, reveal an increase in the mean values for women aged 15-24, 25-39 and 55+ and for men aged 25-39 and 55+.

Figure 18 Mean personal ideal family size in Austria over the period 2001-2011.

This recent increase brings the ideals of the old generations back to replacement levels, but does not change the differences between young and old cohorts in the preference for small and large families, as observed in the previous EB round (Testa 2006). Comparing the oldest (55+) with the young generations (15-39), the share of the preference for no children doubles from $4 \%$ to $9 \%$, while the share of the preference for large families is almost cut in half from $24 \%$ to $13 \%$ (Table A.1.1).
The very low Austrian family size ideals are due to the higher proportions of young women and men preferring smaller families and the lower proportions of those who prefer large families as compared to those of other EU countries (Table A.2.2). Around one in four women aged 25-39 years reports a family with
less than two children as an ideal and only $13 \%$ prefer families with three or more children (Figure 19).

Figure 19 Distribution of women aged 25-39 by ideal family size. 27-EU countries. EB 2011

More in-depth analysis is needed to reconcile these findings with those coming from a different Austrian data source (GGS 2008, see Buber and Neuwirth 2009) which shows values slightly above replacement level. None of these data sources, however, seem to suggest that people in Austria are having as many children as they would like to have (see section 6).

## 11. CHANGES OVER TIME: 2001-2011

A substantial stability in the mean ideal, intended, and actual family size is observed in the EU-15 over the decade 2001-2011 (Figure 20).

In 2011 the mean ideal family sizes are slightly lower than in 2006 (men) or 2006 and 2001 (women and men).

A decrease of mean ultimately intended family size affects only women aged

55 or above and men aged 15-24. A slight decline of mean actual family size concerns only women aged 40 or above (Figure 20).

The temporal stability of the different family size indicators is confirmed also for the 12-NMS (Figure A.1.7) where a slight decline is registered in each of them, especially among men, between 2006 and 2011.

Figure 20 Mean personal ideal, ultimately intended and actual family size. EU-15 and NMS-12.

Greece is the only country showing a clear decline of the mean ideal family size between the 2006 and the 2011 EB rounds: the values go down from 2.3 to 2.1 and from 2.9 to 2.6 for women aged 15 to 24 and 55 or above, respectively; and from 2.5 to 2.1 children and from 2.9 to 2.5 children among men aged 25 to 39 and 55 or above, respectively. In no other EU country there has been such a pervasive and sizeable decline. In Cyprus a decrease of a smaller size is recorded. In most of the other countries, if a decrease is observed, this involves either only women or men, or only people in specific age groups: Belgium (men), Finland, (women), France (men mainly), Malta (women and men in the central age groups), Poland (men) and Slovakia (mainly women), Sweden (women), Portugal (women above age 24 and men aged 40-54). (Figures 21 and Figure A.1.9). In Portugal a decline of the general ideal family size is observed which is indeed more pronounced than that concerning the personal ideal family size. Both Greece and Portugal do experience a decline in the mean ultimately intended family size over the period 2006-2011.

In some countries a temporal increase of the mean personal ideal family sizes is registered (see the previous section for the case of Austria). In Germany the personal ideals observed in 2011 and 2006 are considerable higher than those of the previous round conducted in 2001 (Figure 21). This result, which raises doubts on the reliability of the 2001 data, may be partly due to the different sample design adopted for this country in the 2001 and in the two successive rounds with the size of the eastern Germany sample being halved in the 2006 and 2011 rounds as compared to that of the 2001 (Testa 2006). The family size ideals of women and men aged 2539 observed in the 2011 EB round are still lower (around -0.2) than those found in a
comparable group, ages $25-37$, in a recent German longitudinal study (pairfam 2008/09) (Buhr and Huinink 2010).

In Romania personal family size ideals are higher in 2011 than in 2006 but only for men while for women a slight increase is registered only in the age group 25-39 (Figure A.1.9).

Figure 21 Mean personal ideal family size by gender and age. Several countries.

## 12. CORRELATES OF IDEAL, ACTUAL AND ADDITIONALLY INTENDED FAMILY SIZES

In Table 3 the marginal effects of three different ordered logistic regression models are reported. The outcome variable, coded $0,1,2$, 3 or more, is the ideal family size in the first model, the actual family size in the second model and the additionally intended family size in the third model.

Table 3 Association of socio-demographic characteristics with ideal, actual and additionally intended number of children.

|  | FAMILY SIZES |  |  |  |  |  |

| Enrolled |  |  |  |  |  |  |
|  | -3.7 | $* * *$ | -1.9 | $* * *$ | 1.9 | $* * *$ |
| First cut | -2.3 | $* * *$ | -0.4 | $* * *$ | 3.3 | $* * *$ |
| Second cut | 1.0 | $* * *$ | 2.13 | $* * *$ | 6.2 | $* * *$ |
| Third cut | 23002 |  | 23002 |  | 23002 |  |
| N. cases |  |  |  |  |  |  |

Marginal effects of ordered logistic regression models. Models for ideal family size and additionally intended family size are controlled for actual family size. Models for actual family size are controlled for ideal family size. * $\mathrm{p}<0.05 ; * * \mathrm{p}<0.01 ; * * * \mathrm{p}<0.001$.

As already seen, men have a lower ideal and actual family size than women. The sign of the coefficient reverses for the intended family size suggesting that men are only in a later reproduction phase than women but do not necessarily plan to have a smaller family than women.

Cohabiting, or being single or separated are negatively associated with actual family size. But only separation is negatively
correlated also with additionally intended family size, suggesting that cohabitation does not have a depressing effect on completed family size.

Being highly educated is positively associated with both ideal and intended family size but negatively associated with the actual family size. This result suggests that people with a high level of education are presumably those with the biggest difference between ideal and actual fertility. The effect is also gendered: as compared to their less educated counterparts, highly educated women face more challenges in realising their reproductive ideals than men.

Figure 22 shows the predicted probabilities of different combinations of ideal and actual family size by level of education coming from multinomial regression models whose estimates are not shown in the paper but available upon request. The outcome variable has three categories: 'ideal equal to actual family size', 'ideal greater than actual family size' and 'ideal smaller than actual family size'.

Figure 22 Predicted probabilities of different combinations of ideal and actual family size by level of education. Ages 25-39.

## 13. RELATIONSHIP BETWEEN INDIVIDUALS' SATISFACTION WITH THEIR OWN LIFE AND FAMILY SIZES

In the 2011 EB rounds respondents are asked to report the level of satisfaction about the life they lead ("On the whole, are you very satisfied, fairly satisfied, not very satisfied or not at all satisfied with the life you lead?"). Response options are: 'very satisfied', 'fairly satisfied', 'not very satisfied', and 'not at all satisfied'. A rank of the countries according to the proportion of people very satisfied with their own life is given in Figure A.1.11.

Figure 23 shows the cross-country relationship between women's mean ideal family size and the women's share of life satisfaction for the age group 25-39. As can be seen, there is a positive correlation between the two variables $(\mathrm{r}=0.45)$ : countries with higher proportions of satisfied women are also those in which women prefer larger families. Here satisfied women are those who selected the answer 'very satisfied' in the related item.

A similar positive association is observed among women at older ages (40-54 and 55+). Interestingly, the cross-country relationship mentioned above appear weak and not statistically significant in the men subsample irrespective of the age group

Figure 23 Cross-country relationship between the mean ideal family size and the share of women aged 25-39 satisfied with their own life.

considered (results are available upon request). This finding suggests that for women ideal family sizes and life satisfaction are more closely related each other than for men.

An analogous positive cross-country relationship between mean actual family size and life satisfaction could not be observed for women (or men) aged 25 to 39 . This does not means that a relationship does not exist but only that it does not take a linear shape. Indeed, a positive and significant cross-country correlation is found between the share of women satisfied with their own life, on one hand, and both the share of childless women and that of women with three or more children, on the other hand.

If people aged 40-54 are selected, for whom family size is (almost) completed, a positive cross-country association is detected between the mean actual family size and people's life satisfaction. The relation is statistically significant for men $(r=0.46)$ but not for women ( $\mathrm{r}=0.19$ ) (Figure 24). In the next section these different relationships are investigated in a multivariate setting.

Figure 24 Cross-country relationship between the mean actual family size and the share of men aged 40-54 satisfied with their own life.

## 14. RELATIONSHIP BETWEEN INDIVIDUALS' PERCEPTION OF THEIR COUNTRY'S SOCIO-ECONOMIC

 SITUATION AND THEIR FAMILY SIZESIn the 2011 EB survey interviewed people were asked to report their assessment on several socio-economic aspects of the country they live in. 15 different items are included in the survey question (see the full list in Tables A.1.3, A.1.4 and A.1.5). These assessments are made with reference to the time of the survey, the next twelve months, and the past five years (see Table A.1.2 for question wording).

As shown in Table A.1.3, response options range from 'very good' to 'very bad'. Most of the interviewed people evaluate the current situation either 'rather good' or 'rather bad'. A very tiny minority give a 'very good' evaluation, below $10 \%$ for most of the items. $30 \%$ of the respondents selected this option when they assess the area they live in and $14 \%$ and $13 \%$ of the interviewed people chose it when they evaluate the health care provision and their own job situation, respectively. Almost one out of three respondents evaluate rather bad the cost of living and the employment situation (44\%), the affordability of housing ( $43 \%$ ) and energy ( $45 \%$ ) and the way inequality and poverty are addressed in the country they live in ( $48 \%$ ). There are only very few 'don't know' answers, the only exception being items related to the country's unemployment benefits (15\%) and the individual's job situation (20\%).

Most Europeans have an outlook that is neither optimistic nor pessimistic of the short-term future, i.e., they think that for most of the aspects the situation of their country will stay the same in the next twelve months (Table A.1.4). A future worsening is perceived especially in the cost of living (59\%) and affordability of housing and energy ( $43 \%$ and $53 \%$, respectively).

Most Europeans think that their country's socio-economic situation has been
stable or worsening over the past five years. Their pessimism is particularly pronounced when it come to the provision of pensions ( $52 \%$ ), cost of living ( $80 \%$ ), affordability of energy and housing ( $70 \%$ and $65 \%$, respectively) and the economy and employment situation ( $68 \%$ and $64 \%$, respectively) (Table A.1.5).

In Table A.1.6 the marginal effects of several ordered regression models are reported in which the response is, alternatively, the individuals' satisfaction with their own life (Model 1), the individual's evaluation of: their job situation and their household's financial situation (Model 2); the economy and employment situation in their country (Model 3 ); the provision of pensions, unemployment benefits and heath care in their country (Model 4); and the affordability of energy in their country (Model 5). These items are selected out of the 15 included in the satisfaction question because they seemed more closely related to childbearing and family size issues in a preliminary exploratory analysis. While for Model 1 and Model 5 the item itself is the response, for models 2, 3 and 4, two or three different items are grouped together. The internal consistency of these different items is estimated with Cronbach's Alpha and relatively high values for the reliability coefficients (above 0.70) are obtained, which supports the choice to group them in one single variable. A rank of the countries according a compiled scale of all 15 items is given in Figure A.1.12.

As can be seen in Table A.1.6, older people, highly educated people and people enrolled in education have a more optimistic view of their own life, their household's financial situation, the country' economy and employment situation, the provision of
pension, health and unemployment benefits and the affordability of energy in their country. With the exception of their own life, men evaluate the aspects mentioned above more positively than women. With the exception of their life and their job situation, cohabiting partners assess more positively the various aspects mentioned above than married couples (Table A.1.6).

People with higher ideals are more satisfied with their own life than those who have lower ideals (Figure 25). Moreover, those who prefer large families give a more positive evaluation of their own job and their household's financial situation, the country's economy and employment situation, and the country's health, pension and unemployment benefits (Table A.1.6). As suggested in the previous section, the positive relation between family size ideals and life satisfaction is gendered: men with large family size ideals are more satisfied with their life than those with lower ideals and to a lesser degree than their female counterparts (Table A.1.6).

People who have large families (three or more children) are more concerned about their own job situation and their household's financial situation and about affordability of energy in their country than those who are childless, or have two children or smaller families, respectively. By contrast, they are more satisfied with their own life and more optimistic about the provision of pension, health and unemployment benefits in their country than those with smaller families (Table A.1.6). The relationship between actual family size and satisfaction in life seems to be Ushaped with those childless and with three or more children being more likely to be very satisfied with the life they lead (Figures 25). The positive relation between being childless and being satisfied with their own life is gendered: childless men are more satisfied with their lives than those with children and to a lesser degree than their female counterparts (Table A.1.6).

Figure 25 Individuals' predicted probabilities of being satisfied with their life by ideal or actual family size. Estimates from Model 1 shown in Table A.1.6.

## SUMMARY

This paper uses the 2011 Eurobarometer survey on Fertility and Social Climate to examine the correspondence between personal family size ideal and actual family size. The issue is of highly relevant for social policy making since the persistence of high ideals in a context of declining actual fertility has been identified as a window of opportunity and a justification for the recent attempts to close the gap between fertility ideals and fertility behaviour in Europe.

The EB 2011 data highlighted the following results:

- In Europe, $58 \%$ and $69 \%$ of women and men, respectively, in their prime reproductive ages, 25-39, have a family smaller than that they would like to have. The difference between ideal and actual fertility is 0.9 children for women and 1.3 children for men. At older ages of 40 and above, when family size should be almost completed, around $30 \%$ of women and men have a smaller family size than the one they would have liked to have had, and their mean ideal-actual gap is at around 0.4 and 0.5 children, respectively.
- Men have lower ideals than women but the discrepancy between ideal and actual family size is greater for men than for women in most EU countries. This is in part due to the circumstance that men start building a family later in life than women and, consequently, they have smaller actual family sizes than women at comparable ages. Men's delay in family formation is more than compensated by their lower ideal family sizes in the following countries: Finland, Sweden, Denmark, the Netherlands, Luxembourg, eastern Germany, the Czech Republic and Hungary. As a result, in these countries the sign of the gender
differences in the ideal-actual gap reverses, with women showing a greater difference between ideal and actual fertility than men at ages 40-54. Interestingly, the Netherlands and the Scandinavian countries are also known for their high gender equality systems. Further research is needed to clarify the reasons for men's lower family size ideals in Europe which are confirmed also in the multivariate analysis.
- Education does matter. People with high level of education have fewer children than those with low or medium educational level, but they would like to have more children than their less educated counterparts. This result, which could be caused by the selection process reflecting the fact that early childbearing and large families prevent the achievement of high levels of education, should be further researched. It is worth emphasising that the highest level of discrepancy between ideal and actual family size is observed among the highly educated which makes them an important target group for family-friendly policy measures aiming at closing the idealactual gap.
- A substantial stability or a slight increase over time is observed in the share of people who report a two-child family as an ideal family size. An analogous trend is observed in the share of people who are satisfied with their two-child family size (i.e., those who report this number as their ideal and their actual family size). The reasons for the desirability of this size as well as the hypothesis of a possible future convergence around this two-child norm deserve to be further investigated.

Austria is the only EU country with below-replacement family size ideals. Other
countries, like Bulgaria, the Czech Republic and eastern Germany show below-replacement levels either only for women (Bulgaria), or only for men (the Czech Republic and eastern Germany), and in both cases only for specific age groups. The reasons for Austria's exceptionally low fertility ideals are due to a higher proportion of young people preferring families with less than two children than observed in the other EU countries, which suggests that the below-two-children norm is now most prevalent in Austria. The age differences in the preferences for small (none or one child) and large families (three or more children), which are bigger than those observed in the other EU countries, remained constant over the years 2006-2011. However, the temporal trend in the period 2006-2011, which was actually increasing for both the young and the old generations, might raise doubts on the interpretation of these age differences as a time trend of declining ideals by cohorts. Most importantly, the particularly low levels of ideal family size do not imply a correspondence between ideal and actual fertility in Austria. At age 40 or above the ideal-actual gap, 0.3 children, is only slightly lower than the one registered in the EU-27 as a whole, 0.4 children, but much lower than that computed on the Austrian GGS survey data, 0.7 , for a comparable age group.

- Greece is the only EU country experiencing a pervasive decline of family size ideals in the period 2006-2011. In the other EU countries, the decrease is either of a smaller magnitude, like in the United Kingdom and Cyprus, or involves either only women or men of specific age groups, like in Belgium, Finland, France, Portugal, Sweden and Malta. With the decline of the ideal family size the ideal-actual gap goes down from 2 to 1.6 children among men aged $25-39$, and from 1 to 0.7 , and 0.8 to 0.6
children, for men and women, respectively, aged 40 or above, in the same temporal framework (2006-2011).
- Overall, the current social climate is negative in Europe. Many Europeans give a negative assessment of their country's socio-economic aspects considered in the surveys. The cost of living, the affordability of housing and the situation of economy are badly evaluated by most of the interviewed people. Particularly negative is the perception on how the socioeconomic situation has been developing over the past five years: between $64 \%$ and $80 \%$ of the people formulate a retrospective negative assessment of the cost of living, affordability of housing and energy, and employment and economic situation. Cost of living and affordability of energy are also seen as the most problematic areas for the next short-term future. Europeans tend to be more optimistic about their own life, their personal job situation and their household's financial situation than about their country's socioeconomic conditions. The most optimistic people are, on the one hand, the childless ones and, on the other, those who have or would like to have large families with three or more children. This result, which contains an intrinsic contradiction, needs to be studied in depth in further research.

To conclude, the 2011 EB data on Fertility and Social Climate suggest that there is still room for action by policy makers willing to reduce the gap between ideal and actual family size. When searching for the most effective policies one should take into account that:

1) The discrepancy between ideal and actual family size should be considered not only by comparing the mean ideal and the mean actual fertility but also by examining the
share of people who actually realise their reproductive wishes;
2) Both the size and the prevalence of the ideal-actual gap vary not only across countries but also by gender, age and education as well as by partnership status and other socio-demographic characteristics. Hence, policy measures aimed at helping people to realise their reproductive wishes should not only take into account the level and the share of correspondence between ideal and actual family size in the country and the different institutional, social and demographic contexts in the various countries but, within each of them, they should target the specific sub-groups of people for whom the gap is found to be biggest;
3) In the prime reproductive ages the idealactual gap is driven by the proportion of people who have not yet started a family suggesting that all measures which facilitate the transition to adulthood (finishing education, leaving the parental home, entering the labour market, etc.) might also help to close the ideal-actual gap;
4) The cross-country similarities in the magnitude of the gap between ideal and actual family size may hide substantial differences in the level of each of its two components, suggesting that policy interventions aimed at filling the same amount of the ideal-actual gap might be preferably targeted towards childless couples or couples who already have children depending on the level of the ideal and actual fertility that have generated it;
5) A decline over time in the size of the discrepancy between ideal and actual family size may also be due to a substantial decrease of the ideals, like in Greece, and does not necessarily signal the
absence of a need to help couples in forming their family. By contrast, given the unfavourable situation that caused such abrupt changes, family-friendly policy measures could be particularly recommended in this context;
6) There are two sets of constraints that people face when forming their family: those that people might have already incorporated into their plans (which act through their attitudes, norms and perceived behaviour control, as suggested by the Theory of Planned Behaviour, TPB, proposed by Ajzen 1991; Fishbein and Ajzen 2010), which could be reflected in the ideal-intended gap; and constraints that are related to unexpected events and circumstances that impede people from realising their previously stated fertility plans (the so-called enablers and constraints, according to the TPB). Each of these two sets of factors may require a different kind of policy intervention.

One major shortcoming of this study is related to the small national sample sizes which allow only a breakdown of the national populations by broad age groups. The group of people aged 25-39 mixed up those who may be well into their childbearing years with those who have not yet found a partner and for whom family size ideals remain abstract. Hence, the discrepancy between ideal and actual family size at these ages is based on a family size measure which is incomplete and mixes up the timing with the quantum of fertility. Given that more and more women and men in Europe postpone childbearing, it may be likely that there is no ultimate difference between ideal and actual fertility but only a delay which induces individuals to realise their reproductive wishes later in life. The real correspondence between ideal and actual
family size can indeed only be investigated in a longitudinal setting in which individuals' birth outcomes may be linked to their earlier childbearing wishes. The span of this longitudinal study should be large enough to allow people to complete their family size. Unfortunately, there are no such international long-span longitudinal studies in Europe yet. The Eurobarometer data, which are crosssectional and cannot follow up individuals over time provide a valuable piece of evidence showing that the discrepancy between ideal and actual family size is not only temporary since it does not disappear among women and men at (or near) the end of their reproductive life. The results demonstrate that the observed delay in childbearing, rather than only biasing the measure of the correspondence between ideal and actual fertility, is one of the reasons for the gap between ideal and actual family size. This finding was also found in a recent qualitative study conducted in the US (Diamond-Smith and Astone 2012). The rise over time in the share of people who are uncertain about their childbearing plans, as revealed by the 2011 EB data, is in line with this interpretation as well since uncertainty might just be a reflection in people's minds that delayed childbearing could lead to childbearing forgone (Morgan 1982).

## Acknowledgments

I am grateful to Richard Gisser, Wolfgang Lutz, Julius op de Beke, Dimiter Philipov and Tomáš Sobotka for their useful comments given on an earlier draft of the paper. A special thank goes to Ani Minassian and Lisa Janisch for their helpful suggestions and assistance with the layout and formatting of the document.

[^0]:    European Demographic Research Papers are working papers that deal with all-European issues or with issues that are important to a large number of countries. All contributions have received only limited review.

    Editor: Maria Rita Testa
    Head of the Research Group on Comparative European Demography: Dimiter Philipov

    This material may not be reproduced without the written permission of the author.

[^1]:    Note: With the exception of the intended family size measure, all the questions were worded in exactly the same way as in the previous EB rounds conducted in 2001 and 2006. The intention question was addressed in 2001 and 2006 as follows: "How many children do you (still) intend to have?" Unlike the 2001 and 2006 rounds, the 2011 EB survey did not contain a question on the fertility desires at the beginning of the reproductive career, which was placed in the previous rounds between the personal ideal family size item and the actual family size item, and the question on the age at the birth of the first child, which was placed between the items on actual family size and additionally intended family size.

[^2]:    - Additionally intended number of children $\square$ Number of children needed to reach the ideals
