

II. Quantum origin of structure

recall the idea of inflation

particle horizon

$$\chi_{ph}(t) = \int_{a_i}^a \frac{dt'}{a(t')} = \eta(t) - \eta(t_i)$$

$$= \int_{a_i}^a \frac{1}{aH} da$$

elapsed conformal time

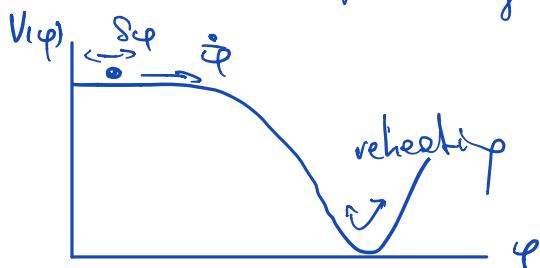

depends on comoving Hubble radius $(aH)^{-1} \propto a^{1/(1+3w)}$

$$a \propto \frac{2}{1+3w} t_i^{1/(1+3w)}$$

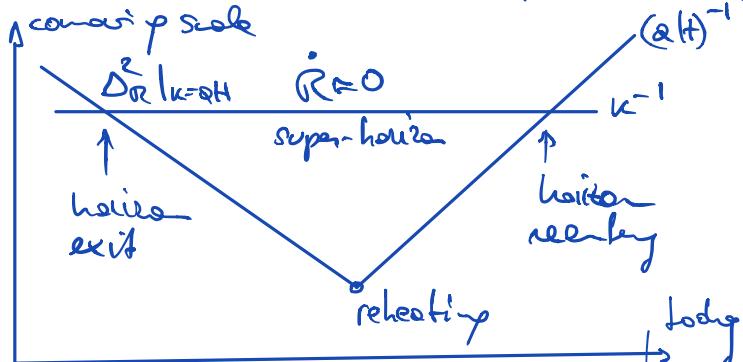

$$\rightarrow -\infty \text{ for } w < -\frac{1}{3}$$

and $a_i \rightarrow 0$

- inflation was originally invented to solve horizon (and flatness) problem.
- quantum fluctuations of scalar field that drives inflation gives seeds of structure

- strategy: compute R_h at horizon exit and make use of constancy of R at superhorizon scales

Canonical quantization of harmonic osc.:

action of h.o. $S = \int dt \left(\frac{1}{2} \dot{x}^2 - \frac{1}{2} \omega(t)^2 x^2 \right) = \int dt L$
 $(m=1 \text{ for convenience; mass on a spring } \omega = k/m)$

$$\text{L.D.E.}: \ddot{x} + \omega^2 x = 0$$

for quantizing the system, one first defines the canonical conjugate momenta to x

$$\Pi = \frac{dL}{dx} = \dot{x} \quad [\text{here it coincides with } p = m\dot{x}]$$

$$\Rightarrow \text{extend } x, \Pi \text{ to ops: } [\hat{x}, \hat{\Pi}] = i\hbar$$

We are in the Heisenberg picture, for which $\hat{x} = \hat{x}(t)$

$$[\hat{x}(t), \dot{\hat{x}}(t)] = i\hbar$$

\hat{x} is expanded in creation & annihilation ops, \hat{a} & \hat{a}^\dagger

$$\hat{x}(t) = \sigma(t) \hat{a} + \sigma^*(t) \hat{a}^\dagger \quad \sigma \dots \text{complex mode fct.}$$

$$\Rightarrow \text{eqns} \begin{cases} \ddot{\sigma}(t) + \omega^2(t) \sigma(t) = 0 \\ \ddot{\sigma}^*(t) + \omega^2(t) \sigma^*(t) = 0 \end{cases}$$

$$\begin{aligned} [\hat{x}, \hat{p}] &= (\sigma \hat{a} + \sigma^* \hat{a}^\dagger)(\dot{\sigma} \hat{a} + \dot{\sigma}^* \hat{a}^\dagger) - (\dot{\sigma} \hat{a} + \dot{\sigma}^* \hat{a}^\dagger)(\sigma \hat{a} + \sigma^* \hat{a}^\dagger) \\ &= \sigma \dot{\sigma}^* \hat{a} \hat{a}^\dagger + \sigma^* \dot{\sigma} \hat{a}^\dagger \hat{a} - \dot{\sigma} \sigma^* \hat{a} \hat{a}^\dagger - \dot{\sigma}^* \sigma \hat{a}^\dagger \hat{a} \quad + \text{less relevant} \\ &= (\underbrace{\sigma \partial_t \sigma^* - (\partial_t \sigma) \sigma^*}_{\text{purely imaginary}}) [\hat{a}, \hat{a}^\dagger] = i\hbar \end{aligned}$$

purely imaginary; normalization can be chosen such that $\hbar = 1$

$$\Rightarrow [\hat{a}, \hat{a}^\dagger] = 1$$

with $\langle v, v \rangle \stackrel{!}{=} 1$

$$\text{where } \langle v, w \rangle = \frac{i}{\hbar} [v^* \partial_t w - (\partial_t v^*) w]$$

Hilbert space built via

$$\left\{ \begin{array}{l} \hat{a}|0\rangle = 0 \quad \text{defines vacuum} \\ |n\rangle = \frac{i}{\sqrt{n!}} (\hat{a}^\dagger)^n |0\rangle \quad ; \text{ eigenstate of number op } \hat{N} = \hat{a}^\dagger \hat{a} \\ \hat{N}|n\rangle = n|n\rangle \end{array} \right.$$

$$\left\{ \begin{array}{l} \hat{a} = \langle v, \hat{x} \rangle = \frac{i}{\hbar} [v^* (\partial_x v) \hat{a} + v^* (\partial_x v^*) \hat{a}^\dagger \\ \quad - (\partial_x v^*) v \hat{a} - (\partial_x v^*) v^* \hat{a}^\dagger] \\ = \frac{i}{\hbar} [v^* \partial_x v - (\partial_x v^*) v] \hat{a} = \langle v, v \rangle \hat{a} = \hat{a} \\ \hat{a}^\dagger = -\langle v^*, \hat{x} \rangle \end{array} \right.$$

Choice of mode func v that solves $x(t)$ is per se not unique, but will simply lead to a different set of \hat{a} & \hat{a}^\dagger via $\hat{a} = \langle v, \hat{x} \rangle \dots$

For $\omega(t) = \omega = \text{const}$ the preferred choice of v is the one that makes $|0\rangle$ the ground state of the Hamiltonian \hat{H}

$$\hat{H} = \dot{x}\pi - L$$

$$= \frac{1}{2} \dot{\pi}^2 + \frac{1}{2} \omega^2 \dot{x}^2$$

$$= \frac{1}{2} [(\dot{v} \hat{a} + \dot{v}^* \hat{a}^\dagger)(\dot{v} \hat{a} + \dot{v}^* \hat{a}^\dagger) + \omega^2 (v \hat{a} + v^* \hat{a}^\dagger)(v \hat{a} + v^* \hat{a}^\dagger)]$$

$$= \frac{1}{2} [(\dot{v}^2 + \omega^2 v^2) \hat{a} \hat{a}^\dagger + (\dot{v}^2 + \omega^2 |v|^2) \hat{a}^\dagger \hat{a} + \text{c.c.}]$$

act on $|0\rangle$ with $\hat{Q}|0\rangle = 0$

$$\hat{H}|0\rangle = \frac{1}{2}(\dot{\psi}^2 + \omega^2\psi^2)^* \hat{Q}^\dagger \hat{Q} + (|\psi|^2 + \omega^2|\psi|^2)|0\rangle$$

if $|0\rangle$ is to be an eigenstate of \hat{H} , first term needs to vanish

$$\Rightarrow \dot{\psi} = \pm i\omega\psi$$

$$\Rightarrow \langle \psi, \psi \rangle = \mp 2\omega |\psi|^2 ; \text{ for } \langle \psi, \psi \rangle > 0 \text{ choose + sign}$$

$$\Rightarrow \psi(t) = \sqrt{\frac{\hbar}{2\omega}} e^{-i\omega t}, \quad \langle \psi, \psi \rangle = 1$$

$$\Rightarrow \hat{H} = \hbar\omega \left(\hat{N} + \frac{1}{2} \right); \text{ occupies minimum energy } \hbar\omega/2$$

Quantum fluctuations around the ground state ($\langle \hat{x} \rangle = 0$)

$$\text{Consider } \langle |\hat{x}|^2 \rangle \equiv \langle 0 | \hat{x}^\dagger \hat{x} | 0 \rangle$$

$$\begin{aligned} &= \langle 0 | (\underbrace{\psi^* \hat{Q}^\dagger + \psi \hat{Q}}_{\psi^\dagger \hat{Q}^\dagger}) (\psi \hat{Q} + \psi^* \hat{Q}^\dagger) | 0 \rangle \\ &= |\psi|^2 \langle 0 | \hat{Q} \hat{Q}^\dagger | 0 \rangle \\ &= |\psi|^2 \langle 0 | [\hat{Q}, \hat{Q}^\dagger] | 0 \rangle = |\psi|^2 \end{aligned}$$

$$\Rightarrow \langle |\hat{x}|^2 \rangle = |\psi|^2 = \frac{\hbar}{2\omega} \quad \text{quantum fluctuations of harmonic oscillator}$$

Quantum fluctuations during inflation

Consider an inflationary period that is driven by scalar field φ :

$$S_\varphi = \int d^4x \sqrt{-g} \left[-\frac{1}{2}R + \frac{1}{2}g^{rr}(\partial_r \varphi)(\partial_r \varphi) - V(\varphi) \right]$$

$$\text{units } M_p = \frac{1}{8\pi G} = 1.$$

A brute force way would be e.g. take Newtonian gauge with scalar perturb. ϕ and φ & perturbed inflato field $\varphi = \bar{\varphi}(\eta) + \delta\varphi(\vec{x}, \eta)$ and work through the eqs. However, it turns out that the system can be reduced to 1 dynamical variable [e.g. absence of anisotropic stress in scalar theory implies $\phi = \varphi$ and further constraint eq. reduces $\delta\varphi$ & ϕ to 1 variable].

An alternative way to treat inflationary perturbations is to choose the following gauge (see Maldacena astro-ph/0210603)

$$\underline{\delta\varphi=0} \quad \underline{g_{ij} = -\dot{\alpha}^2 \left[(1 - 2R) \delta_{ij} + h_{ij} \right]}$$

↑
consuming coordinate perturbations
as before

$$\partial_i h_{ij} = 0 \quad h_{ii} = 0 \quad \text{tensor perturbations}$$

Only one metric perturbation $R(t, \vec{x})$ to follow, with the important property that it is constant on superhorizon-scales.

For quantization, we need the action S in second order in the perturbations. This is laborious, and here we simply quote the result

$$S = \frac{1}{2} \int d^4x \alpha^3 \frac{\dot{\Phi}^2}{H^2} \left[\dot{R}^2 - \frac{1}{\dot{\alpha}^2} (\partial_i R)^2 \right] + \text{higher order}$$

The action can be brought into canonical form by defining so-called "Rubakov variables"

$$\underline{\sigma \equiv z R} \quad \text{with} \quad \underline{z = \alpha \frac{\dot{\bar{\varphi}}}{H} = \alpha \frac{\bar{\varphi}'}{\dot{x}}} \quad (\partial_2 A = A')$$

[recall $\frac{dt}{d\eta} = a \quad \dot{A} = \frac{1}{a} A'$

\Rightarrow in terms of conformal time

$\dot{x} = \frac{\alpha'}{\bar{\varphi}} = \alpha H$

$$\underline{S = \frac{1}{2} \int d\eta d^3x \left[(\sigma')^2 + (2; \sigma)^2 + \frac{z''}{z} \sigma^2 \right] + \dots}$$

= action of a harmonic oscillator with a time-dep. mass

$$m^2(\eta) = -\frac{z''}{z} \approx -\frac{2}{\eta^2} \quad (\text{de Sitter})$$

\Rightarrow even in terms of Fourier-components $\sigma_\kappa(\eta) = \int d^3x e^{-i\vec{k}\cdot\vec{x}} \sigma(\eta, \vec{x})$

$$\underline{\sigma_\kappa'' + \left(k^2 - \frac{z''}{z}\right) \sigma_\kappa = 0} \quad \text{"Rubakov-Sorboi-eqns."} \quad k=|\vec{k}|$$

$$\underline{\omega_\kappa^2(\eta) = k^2 - \frac{z''}{z}}$$

classical evolution:

$$\text{subhorizon } k^2 \gg |z''/z| : \sigma_\kappa'' + k^2 \sigma_\kappa = 0$$

$\Rightarrow \sigma_\kappa \propto e^{\pm i k \eta}$ oscillate

$$\text{superhorizon } k^2 \ll |z''/z| : \frac{\sigma_\kappa''}{\sigma_\kappa} = \frac{z''}{z} \approx \frac{2}{\eta^2}$$

$$\Rightarrow \sigma_\kappa \propto z \propto \frac{1}{\eta}$$

[growing solution ; η runs from negative values to 0 during inflation ; decaying solution $\sigma_\kappa \propto \eta^2$]

$$\Rightarrow R_\kappa = \frac{1}{\epsilon} \omega_\kappa \approx \text{const}$$

perturbative freedom at superhorizon scales

Canonical quantization of σ :

o) canonical conj. momenta $\Pi = \dot{\sigma}'$

o) Hamiltonian becomes $\hat{H}(\eta) = \frac{1}{2} \int d^3x [\dot{\Pi}^2 + (\partial_i \dot{\sigma})^2 + m^2(\eta) \dot{\sigma}^2]$

o) Equal-time commutative relation:

$$[\hat{\sigma}(\tau, \vec{x}), \hat{\Pi}(\tau, \vec{x})] = i \delta^{(3)}(\vec{x} - \vec{y})$$

$$\hat{G}(\vec{x}, \eta) = \int \frac{d^3k}{(2\pi)^3} [v_u(\eta) \hat{a}_u e^{i\vec{k} \cdot \vec{x}} + v_u^*(\eta) \hat{a}_u^+ e^{-i\vec{k} \cdot \vec{x}}]$$

$$\Rightarrow [\hat{a}_{\vec{k}}, \hat{a}_{\vec{k}'}^+] = (2\pi)^3 \delta(\vec{k} - \vec{k}'); \text{ others } 0$$

for normalization of $v_u(\eta)$ as $\langle v_u, v_u \rangle = 1$

one of two boundary conditions of
Bilbaoz - Sasaki Eq (2nd order ODE)

o) Hilbert-space is built by defining the vacuum state

$$\hat{a}_{\vec{k}} |0\rangle = 0$$

and repeated application of creation ops

$$|m_{\vec{k}_1} n_{\vec{k}_2} \dots \rangle = \frac{1}{\sqrt{m! n! \dots}} \hat{a}_{\vec{k}_1}^+ \hat{a}_{\vec{k}_2}^+ \dots |0\rangle$$

if once mode-fields are selected, vacuum unambiguous; however, $\langle \sigma, \sigma \rangle = 1$ not sufficient.

To see this, consider $u_n(\eta) = d_n \sigma_n(\eta) + \beta_n \sigma_n^*(\eta)$
with $|d_n|^2 + |\beta_n|^2 = 1$

$\Rightarrow \langle u, u \rangle = 1$ normalization unaffected and

$$\hat{G}(\eta, \vec{x}) = \int \frac{d^3 k}{(2\pi)^3} \left[\hat{b}_{\vec{k}} u_n(\eta) e^{i \vec{k} \cdot \vec{x}} + \hat{b}_{\vec{k}}^+ u_n^*(\eta) e^{-i \vec{k} \cdot \vec{x}} \right]$$

where b 's satisfy equivalent commutation relations as a 's;
both are related by so called "Bogoliubov transformations"

$$\hat{a}_{\vec{n}} = d_n^* b_{\vec{n}} + \beta_n \hat{b}_{-\vec{n}}^+ \quad \text{and h.c.}$$

and both can be used to construct Hilbert space via $\hat{a}_n |0\rangle = 0$ or

$$\hat{b}_n |0\rangle = 0$$

$\Rightarrow "b\text{-vacuum}"$ contains α -particles

$${}_b \langle 0 | \hat{N}_n^{(\alpha)} | 0 \rangle_b = \underbrace{|\beta_n|^2}_{\text{density of } \alpha\text{-particles}} \underbrace{\delta(0)}_{\text{volume factor}}$$

Physical vacuum:

for the harmonic osc. at the beginning it was the condition that \hat{H} is minimized $\Rightarrow \sigma_n(t) = \frac{1}{\sqrt{2\omega_n}} e^{-i\omega_n t} \quad \omega_n = \text{const}$

Now we face $\omega_\kappa = \omega_\kappa(\eta)$, so using the above solution implies $\Omega >_{\eta_1} \neq \Omega >_{\eta_0}$ and $\Omega >_{\eta_0}$ is not the lowest energy state at a later time η .

Explicit time dep. of $\hat{H}(\eta)$: energy of harmonic osc. is not conserved but is increasing with the gravitational field
(this can lead to "gravitational redshift" of particles where the energy is supplied by the classical grav. field)

Zero-point fluctuations in de Sitter phase

$$\omega_\kappa^2(\eta) = \kappa^2 - \frac{\alpha''}{2} \approx \kappa^2 - \frac{\alpha''}{\eta^2} = \kappa^2 - \frac{2}{\eta^2}$$

at early times, all modes were subhorizon ($k\eta \ll 1$)

$$\Rightarrow \omega_\kappa^2(\eta) \approx \kappa^2 - \frac{2}{\eta^2} \rightarrow \kappa^2 = \text{const, time-indep. freqn.}$$

$$\Rightarrow \text{eom: } v_\kappa'' + \kappa^2 v_\kappa = 0$$

$$\Rightarrow \text{harmonic osc. solution minimize } \hat{H}: v_\kappa = \frac{1}{\sqrt{2\kappa}} e^{-ik\eta}$$

\Rightarrow Fullhamer-Sasaki eqn is solved with initial cond.

$$\lim_{\eta \rightarrow -\infty} v_\kappa(\eta) = \frac{1}{\sqrt{2\kappa}} e^{-ik\eta} \Rightarrow \text{"Bunch-Davies vacuum"}$$

The solution to $v_\kappa'' + (\kappa^2 - \frac{2}{\eta^2}) v_\kappa = 0$ obeying this initial condition is

$$v_k(\eta) = \frac{e^{-ik\eta}}{\sqrt{2k}} \left(1 - \frac{i}{k\eta} \right) .$$

On superhorizon scales

$$\lim_{k\eta \rightarrow 0} v_k(\eta) = \frac{1}{i\sqrt{2}} \frac{1}{k^{3/2}\eta}$$

To compute the power-spectrum as a fct. of k , instead of $v(\vec{x}, \eta) \rightarrow \hat{v}(\vec{x}, \eta)$ we may promote the Fourier-compact to operators $v_k \rightarrow \hat{v}_k = v_k(\eta) \hat{a}_k + v_k^*(\eta) \hat{a}_{-k}^\dagger$ (the \hat{a} 's fulfill the same commutation relations as before)

$$\begin{aligned} \langle 0 | \hat{v}_{\vec{k}} \hat{v}_{\vec{k}'} | 0 \rangle &= \langle 0 | (v_k(\eta) \hat{a}_{\vec{k}} + v_{-k}^*(\eta) \hat{a}_{-\vec{k}}^\dagger) (v_{k'}(\eta) \hat{a}_{\vec{k}'} + v_{-k'}^*(\eta) \hat{a}_{-\vec{k}'}^\dagger) | 0 \rangle \\ &= v_k v_{-k'}^* \langle 0 | [\hat{a}_{\vec{k}}, \hat{a}_{-\vec{k}'}^\dagger] | 0 \rangle = v_k v_{-k'}^* \langle 0 | [\hat{a}_{\vec{k}}, \hat{a}_{-\vec{k}'}] | 0 \rangle \\ &= (2\pi)^3 |v_k|^2 \delta^{(3)}(\vec{k} + \vec{k}') \\ &= (2\pi)^3 P_\sigma(k) \delta^{(3)}(\vec{k} + \vec{k}') \end{aligned}$$

$$\Rightarrow P_\sigma(k) = |v_k|^2 \rightarrow \frac{1}{2k^3} \frac{1}{\eta^2} = \frac{3e^2}{2k^3} = \frac{(\Omega H)^2}{2k^3} \quad (\text{superhorizon})$$

$$\text{or, in terms of the dim-less quantity } \Delta_\sigma^2(k) = \frac{k^3}{2\pi^2} P(k)$$

$$\Delta_\sigma^2 = \Omega^2 \left(\frac{H}{2\pi} \right)^2$$

Now we are in a position to compute the power-spectrum of R at "horizon crossing" at $\eta = \eta_*$, $\Omega H \Big|_{\eta_*} = k$ after which it is conserved

$$R = \frac{H}{\dot{\varphi}} \frac{\Omega}{\Omega} \Rightarrow \Delta_R^2(k) = \left(\frac{H}{2\pi} \right)^2 \left(\frac{H}{\dot{\varphi}} \right)^2 \Big|_{k=\Omega H}$$

$$\text{or } P_R(k) = \frac{1}{2k^3} \frac{H^4}{\dot{\varphi}^2} \Big|_{k=0H}$$

Different k -modes exit the horizon at slightly different times when ∂H has a different value; for slow roll inflation this procedure gives the correct result; in other cases one needs to numerically integrate Bullock-Sasaki eqs.

Slow-roll inflation:

recall from earlier lectures $\dot{H} = -\frac{1}{2} \dot{\varphi}^2$ (using Friedmann & eqn) $4\pi G = \frac{1}{2}$

$$\Rightarrow \Delta_R^2 = \left(\frac{H}{2\pi} \right)^2 \left(-\frac{1}{2} \frac{H^2}{\dot{H}} \right) \Big|_{k=0H}$$

for accelerated exp.

we have the slow roll parameters $\varepsilon = -\frac{\dot{H}}{H^2} \ll 1$ $\eta = \frac{\dot{\varepsilon}}{H\varepsilon} \ll 1$

$$\Rightarrow \Delta_R^2(k) = \frac{1}{8\pi^2} \frac{H^2}{\varepsilon} \Big|_{k=0H}$$

scale invariant spectra $\propto k^0$

up to corrections from the time dependence of H & ε

deviations from scale invariance measured by so-called "spectral index" n_s ($n_s = 1$... scale inv.)

$$n_s - 1 = \frac{d \ln \Delta_R^2}{d \ln k}$$

slow
roll

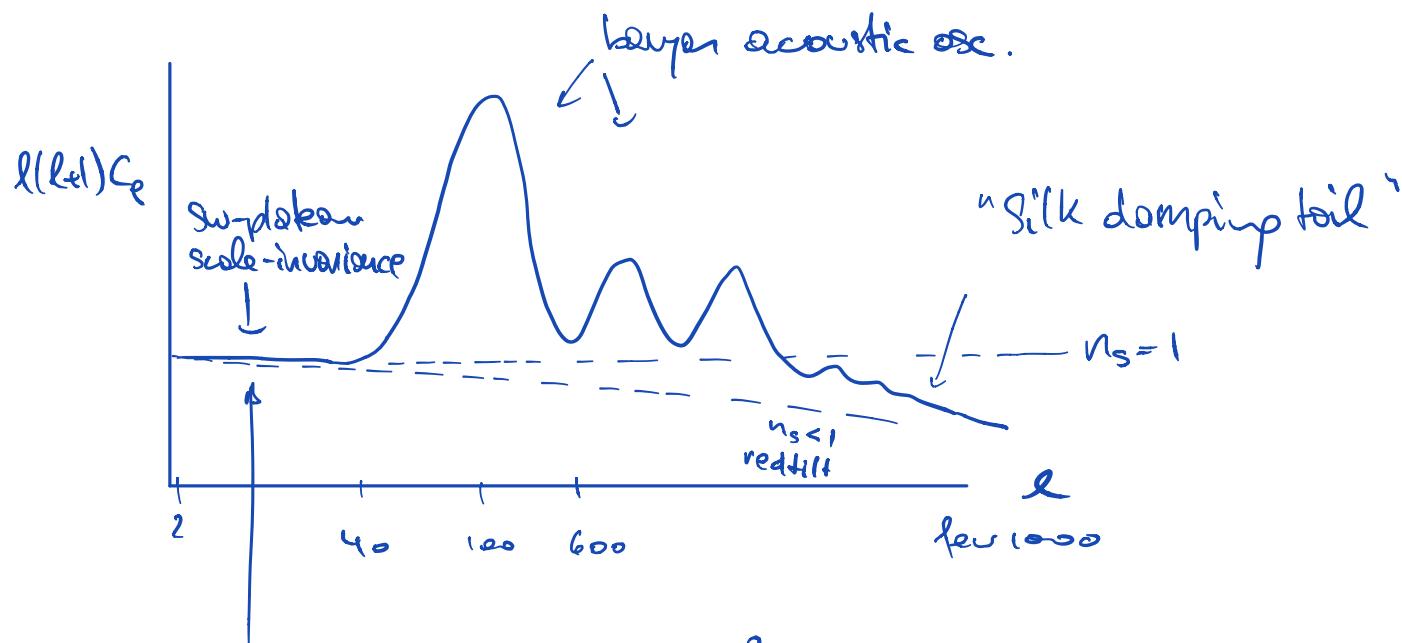

$$-2\varepsilon - \eta$$

↑
↑

computable, once V is specified

Simple models of inflation predict $n_s < 1$ ("red tilted")

CMB measurements:

\Rightarrow amplitude of spectrum $D_R^2 = 2,19(6) \cdot 10^{-9}$ } Planck
 $n_s = 0,968 \pm 0,006$

Tensor perturbations h_{ij} :

Expanding the Einstein Hilbert action in h_{ij} yields

$$S = \frac{\pi p^2}{8} \int d\eta d^3x \alpha^2 \left[(h_{ij}')^2 - (\partial_\eta h_{ij})^2 \right] + \text{higher order}$$

(we have re-introduced πp to make h_{ij} dimensionless)

Fourier-expansion:

$$h_{ij} = \int \frac{d^3k}{(2\pi)^3} \sum_{s=t_1, x} \Sigma_{ij}^s(k) h_{\vec{k}}^s(\eta) e^{i\vec{k} \cdot \vec{x}}$$

$$\Sigma_{ii} = 0 ; \quad k^i \Sigma_{ij} = 0 \quad \Sigma_{ij}^s \Sigma_{ij}^{s'} = 2 \delta_{ss'}$$

To get canonically normalized fields $\omega_{\vec{k}}^s = \frac{\alpha}{2} \pi p h_{\vec{k}}^s$

$$\Rightarrow S = \sum_{s=+,x} \frac{1}{2} \int d\eta d^3k \left[(\omega_k^{s'})^2 - \left(k^2 - \frac{\alpha''}{\alpha} \right) (\omega_k^s)^2 \right]$$

$\underbrace{\quad}_{\omega_k^s(\eta)}$

$$\text{de Sitter: } \frac{\alpha''}{\alpha} = \frac{2}{\eta^2}$$

\Rightarrow precisely what we had for scalar perturbations
(two copies of it for the 2 pol.)

$$P_0 = \frac{1}{2k^3} (\alpha H)^2 \Big|_{k=\alpha H}$$

\Rightarrow tensor power spectrum

$$P_t = P_h \cdot 2 = \frac{4}{k^3} \frac{H^2}{\eta_p^2} \Big|_{\alpha H = k} \quad \text{or} \quad \Delta_t^2(k) = \frac{2}{\pi^2} \frac{H^2}{\eta_p^2} \Big|_{k=\alpha H}$$

↑
rels

observable: "tensor-to-scalar ratio" r (via CMB "B-modes")

$$r = \frac{\Delta_t^2(k)}{\Delta_R^2(k)} \begin{matrix} \leftarrow \alpha H^2 \sim V_{\text{infl}} \\ \leftarrow \text{fixed by obs} \end{matrix}$$

$$\text{Slow-roll: } r = 16 \epsilon \Big|_{k=\alpha H}$$

\Rightarrow direct measure of the energy scale of inflation

$$V^{1/4} \sim \left(\frac{r}{0.01} \right)^{1/4} \cdot 10^{16} \text{ GeV}$$

(future CMB-obs will probe to $r \sim 10^{-3}$)

Literature :

- Weinberg "Cosmology"
everything calculated, but notation different from everyone else ; great book
- Mukhanov "Physical Foundations of Cosmology"
focus on derivations ; very comprehensive
- Mukhanov "Quantum effects in gravity"
more on last chapter and related topics
- Baumann lectures on inflation (arXiv)
very pedagogical ; parts taken from Mukhanov
last lecture taken from here ; other lectures inspired from here as well
- Dodelson "Modern Cosmology"
very pedagogical ; walks with distribution functions for photons
⇒ heavily aimed towards CMB
