

# Short- and medium term effects of informal care provision on health

Hendrik Schmitz   Matthias Westphal

Universität Duisburg–Essen & CINCH

28.11.2013

Health, Education and Retirement over the Prolonged Life Cycle – Vienna

- Low birth rates and prolonged life cycle: population ageing
- ⇒ strong implications for the labor market and social security systems.
- Long-term care is one important part
  - Publicly funded costs of long-term care in the EU27 increase from 1.2% of GDP to 2.5% in 2060

# Motivation II

in Germany:

- 2011: 2,32m receive long-term care (LTC) services in total

- 1,54m (65%) are cared by relatives (1,05m exclusively)

## Research question

Is there any negative health effect for informal caregivers?

## Economic Studies

- Coe und Van Houtven (2009), Do et al. (2013): care and diseases
- Van Houtven et al. (2005); Schmitz und Stroka (2013): care intensity and drug prescription
- Van den Berg and Ferrer-i-Carbonell (2007); Bobinac et al. (2010); Leigh (2010): care and well-being

## Medical studies: many, but:

- Small, non-representative samples
- Descriptive analysis, cross-section
- Focus on dementia patients

## Own contribution:

- Medium-term effects

## Socio-economic Panel (SOEP)

- Representative household survey with currently 22,000 individuals from Germany
- Covers topics on health, labor, education, income, etc.
- Waves 2002-2010

## Outcome variable: health

- Version of the SF12v2-questionnaire
- Summary scale for mental (MCS) and physical health (PCS)
- Range between 0 and 100, mean = 50, std. dev. = 10

Care in the SOEP: “What is a typical day like for you? How many hours do you spend on care and support for persons in need of care?”

Matching algorithm (Propensity score, Gauß-Kernel)

- $T = \begin{cases} 1, & \text{if provided at least 2hrs care in } t = 0 \\ 0, & \text{else} \end{cases}$

We would like to know  $ITE_i = Y_{i1} - Y_{i0}$

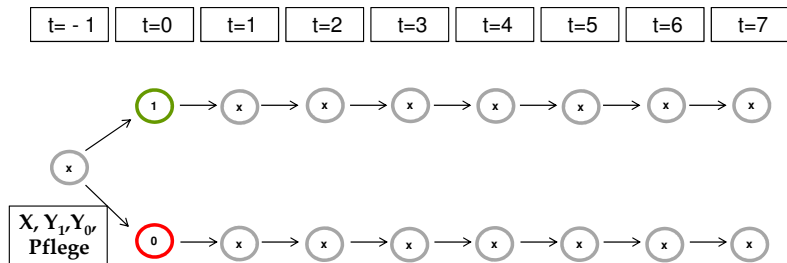

- $Y_{i1}$ : Outcome of  $i$  with care,
- $Y_{i0}$ : Outcome of  $i$  without care

Instead, we focus on the  $ATT = E(Y_1 - Y_0 | T = 1)$ .

Main assumption: CIA

$$Y_0, Y_1 \perp\!\!\!\perp T | X \tag{1}$$

# Time dimension and selection issues

Selection of healthy individuals into care

⇒ Matching on outcome variables  $t - 1$  (pre-treatment)

Selection out of care

⇒ No problem

Further unobserved heterogeneity

⇒ Stratified estimation

# Time dimension

Only women are considered

	t=0	t=1	t=3	t=5	t=7
Hours of care = 0	29,080	26,667	18,956	11,455	5,194
Hours of care = 1	862 (= 41%)	800	564	357	160
Hours of care = 2	507 (= 24%)	479	317	197	85
Hours of care = 3	203 (= 10%)	193	140	81	36
Hours of care = 4	167 (= 8%)	152	100	53	24
Hours of care > 4	358 (= 17%)	331	211	111	53
All observations	31,177	28,622	20,288	12,254	5,552

Source: SOEP, own calculations. Number in parentheses is the share among all individuals with positive hours of care. Hours of care are measured in  $t = 0$  only.

# Why a static model?

In principle, a dynamic approach by Lechner and Miquel (2010) or Lechner (2009b) conceivable

$t = -1$     $t = 0$

# Why a static model?

In principle, a dynamic approach by Lechner and Miquel (2010) or Lechner (2009b) conceivable

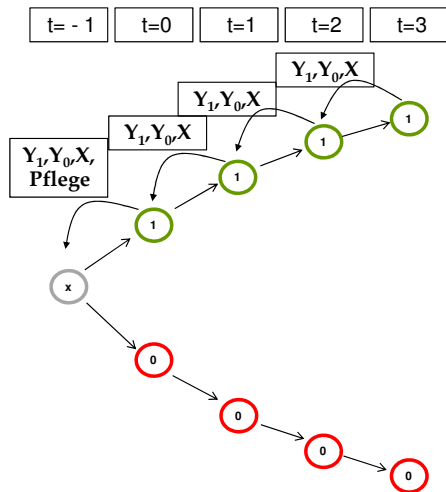

# Why a static model?

In principle, a dynamic approach by Lechner and Miquel (2010) or Lechner (2009b) conceivable

# Why a static model?

# Why a static model?

# Why a static model?

# Why a static model?

# Why a static model?

To sum up

- comparing each of the  $2^8 = 256$  different paths is not manageable
- observations in each path are very small
- Even then, we could not model the yearly transitions appropriately

Thus, we are able to answer:

- What is the average effect of care in one year on health in later years?
- not possible: What is the average effect of different years of care?

# Matching variables

Why do people care?

1. Because they have to
2. ... and they want to
3. ... and they are able to.

Variables for 1

- Mother alive, father alive, age of parents
- Number of sisters, number of brothers

Variables for 2

- Socio-economics characteristics (age, family status, education, labor force participation)
- Personality traits (BIG 5, reciprocity, acceptance of private participation in health care)

Variables for 3

- MCS, PCS, health satisfaction

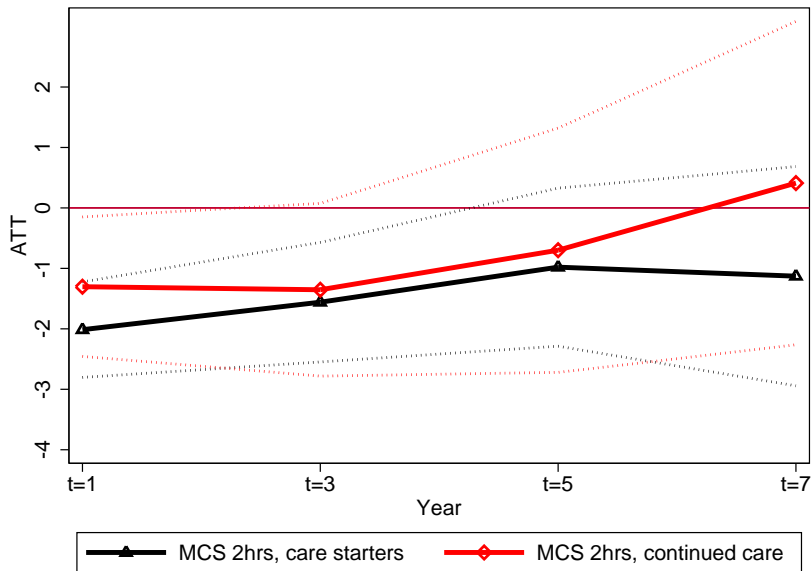

# Kontrollvariablen

# Results: MCS

# Results: MCS

# Results: PCS

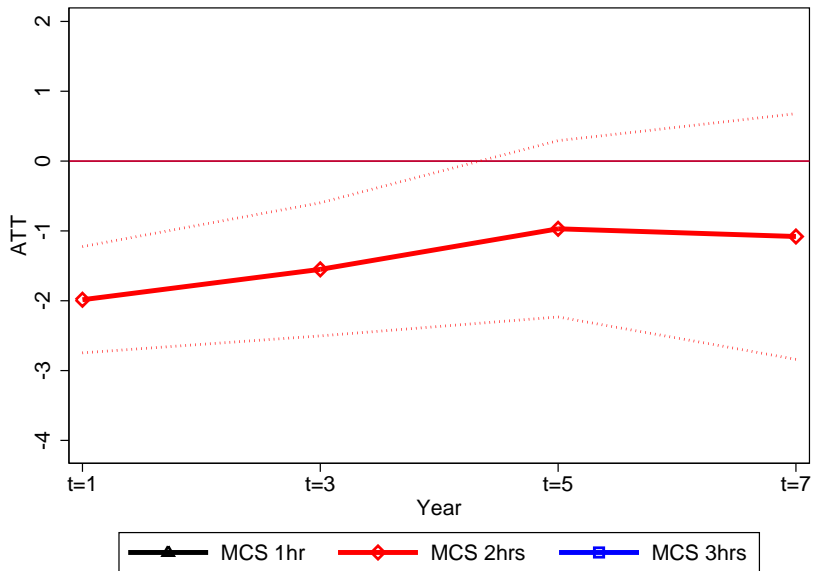

# Results: PCS

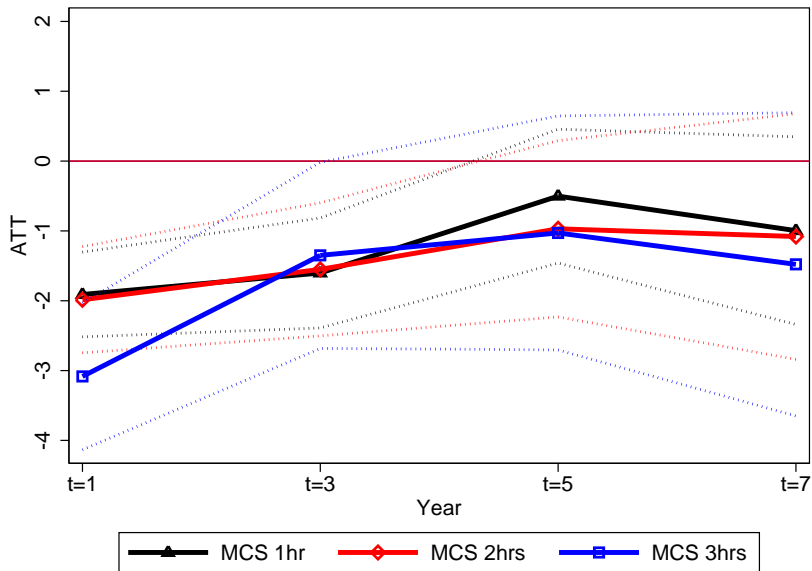

# Results: MCS for different care intensities

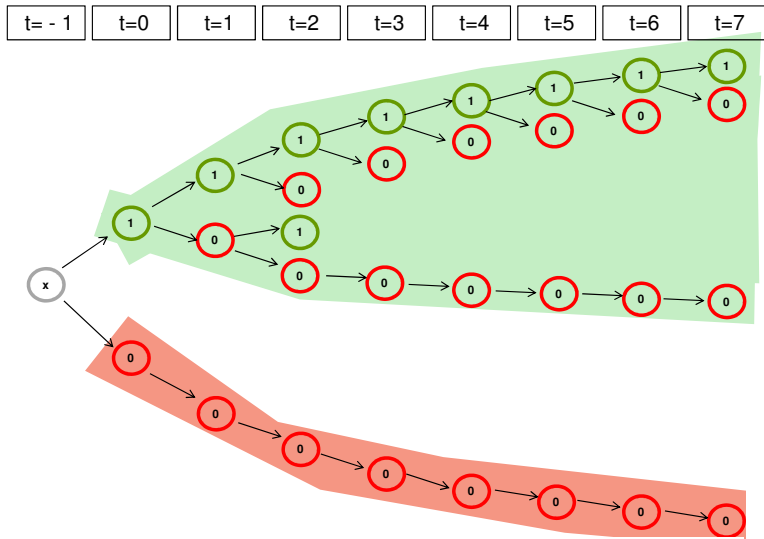

# Results: MCS for different care intensities

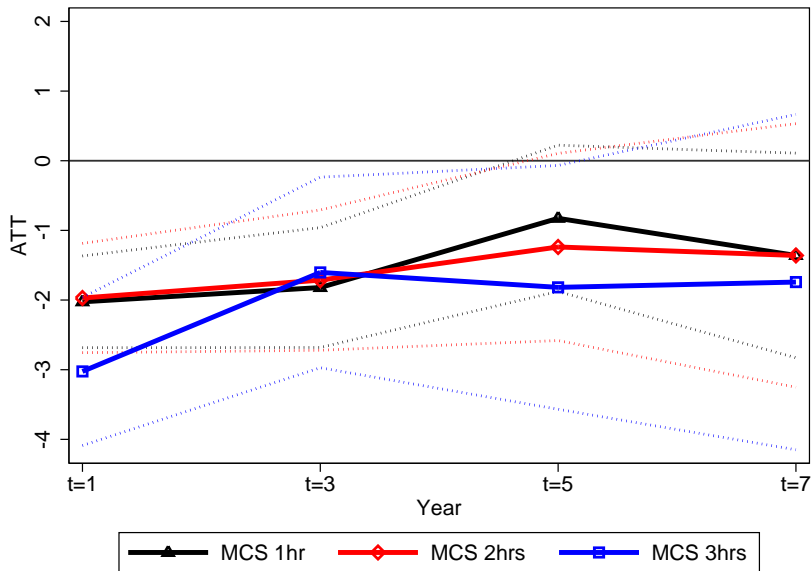

# Results: MCS for different care intensities

# Alternatively

# Results: MCS, control group of never carers

## Main results so far:

- Considerable short-term effects of informal care on mental health of female caregivers
- Effects increase with more care intensity
- Irrespective of the intensity: effects attenuate over time (and are insignificant)

## Why is that?

- Majority has stopped caring after 3 years
- Short-term effects are driven by active care (and maybe by the bereavement effect)
- There is no “scarring effect”

Sensitivity analysis (Ichino et al., 2008). Is a potential failure of the CIA crucial?

Assessment: slightly relax the unconfoundedness assumption. We assume that

$$Y_0, Y_1 \not\perp\!\!\!\perp T|X$$

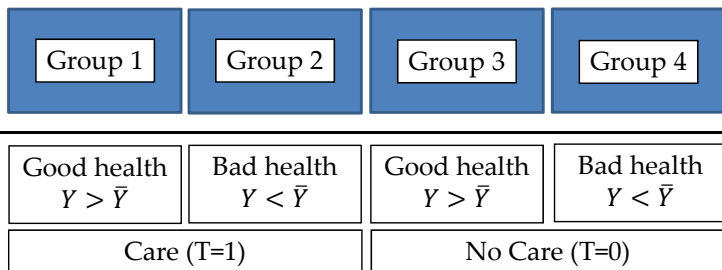

but the failure is due to an unobserved binary variable  $U$ . Could we condition on it, we had

$$Y_0, Y_1 \perp\!\!\!\perp T|(X, U) \quad (1')$$

Example:  $U$  is genetic endowment ( $U = 1$  good,  $U = 0$  bad).

Idea: make some assumptions on  $U$  (in particular how it drives the selection and the outcome), simulate and match on it.

# Sensitivity Analysis

# Sensitivity Analysis

$$p = \Pr(U=1 \mid \text{group})$$

---

Good health $Y > \bar{Y}$	Bad health $Y < \bar{Y}$	Good health $Y > \bar{Y}$	Bad health $Y < \bar{Y}$
Care (T=1)		No Care (T=0)	

# Sensitivity Analysis

$$p = \Pr(U=1 \mid \text{group})$$

---

Good health $Y > \bar{Y}$	Bad health $Y < \bar{Y}$	Good health $Y > \bar{Y}$	Bad health $Y < \bar{Y}$
Care (T=1)		No Care (T=0)	

# Sensitivity Analysis

$$p = \Pr(U=1 \mid \text{group})$$

Good health $Y > \bar{Y}$	Bad health $Y < \bar{Y}$	Good health $Y > \bar{Y}$	Bad health $Y < \bar{Y}$
Care (T=1)		No Care (T=0)	

# Justification of choice of $d$ and $s$

Assumption: unobserved  $U$  has a stronger effect than each single observable (but not too strong). Choices:

1. Outcome effect = 0.2 (0.3) and Selection effect = 0.2 (0.3)
2. Outcome effect = 0.2 (0.3) and Selection effect = -0.2 (-0.3)

Table : Distribution of  $p_{ij}$  across control variables in the sample

	<b>d</b>	<b>s</b>	<b>Effect</b>
Mother alive	-0.05	-0.05	(+)
Number of sisters	0.01	-0.03	(-)
Age	0.21	0.19	(+)
Married	0.19	0.16	(+)
Divorced	-0.03	-0.02	(+)
Full time	-0.04	-0.07	(+)
MCS	-0.03	-0.09	(+)
PCS	-0.12	-0.12	(+)

# Sensitivity Analysis: Results

# Sensitivity Analysis: Results

# Sensitivity Analysis: Results

# Sensitivity Analysis: Results

# Sensitivity Analysis: Results

## Summary:

- Short-term effects of informal care on mental health (females)
- After about 5 years they are back at to the base level
- Short-term effects increase in care intensity, medium-term effects do not
- No significant effects for physical health
- Results hold for certain deviations from the CIA assumption

Main limitations: Estimated effect is compound of many different effects

- Intensity and duration
- Relation to care recipient
- Combination of care with other burdens (care & full-time work)

Thank you for your attention

## Backup slides

# Care durations in the balanced panel

Years of consecutive care as of t=0	1	2	3	4	5	6	7	8	Total
Uncensored Obs.	309	51	24	9	7	7	5	-	412
Share	75%	12%	6%	2%	2%	2%	1%	-	100%
Censored Obs.	265	244	84	108	37	42	12	23	815
Share	33%	30%	10%	13%	5%	5%	1%	3%	100%
Total Obs.	574	295	108	117	44	49	17	23	1227
Share	47%	24%	9%	10%	4%	4%	1%	2%	100%

Source: SOEP, own calculations. Uncensored individuals did not provide care in  $t = -1$  and stopped caregiving some time before  $t = 7$ . Therefore, the maximum observable care duration is 7 years.

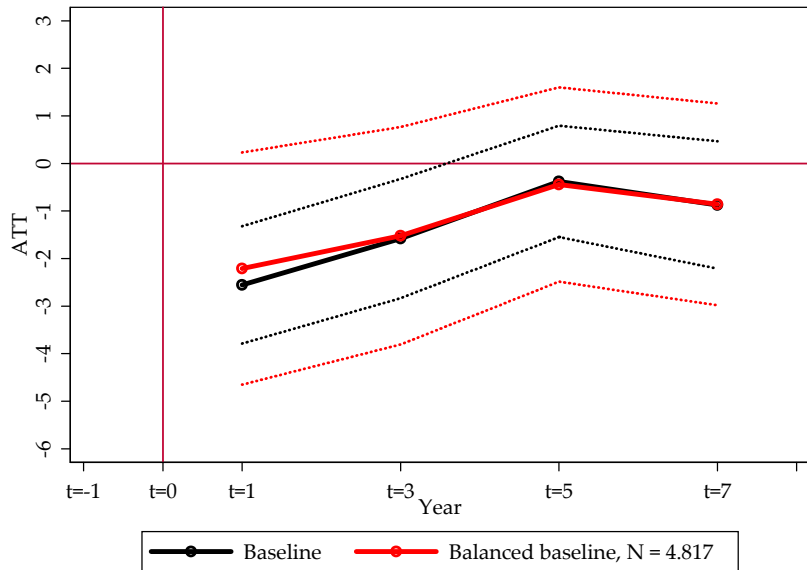

Effects in  $t = 1$  (baseline specification)

- 2 hours: -2.00
- 3 hours: -3.02

Some results from the literature using the MCS measure

- Schmitz (2011): Unemployment (plant closure):  
+0.5 to -1.5 (insign.)
- Marcus (2013): Unemployment of couples (plant closure):  
-2.7 (sign.)
- Lechner (2009): Sport participation, 16 years after:  
+0.9 (insign.)

# Results: MCS, balanced and unbalanced

$$A\hat{T}T = \frac{1}{n_1} \sum_{i \in I_1} \left[ Y_{1i} - \sum_{j \in I_0} \omega(i, j) \cdot Y_{0j} \right]$$
$$\omega(i, j) = \frac{K\left(\frac{p_i - p_j}{h}\right)}{\sum_{\{j \in D=0\}} K\left(\frac{p_i - p_j}{h}\right)}, \quad K(u) = \exp(-u^2/2)$$

Exploit the double robustness property (Bang & Robins, 2005)

double Robustness Property:

$$\hat{\beta}_{ATT} = (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1}\mathbf{X}'\Delta y$$

- $\hat{ATT}$ : weighted average
  - control again for the confounding factors
- ⇒ doubly consistent estimator
- robust standard errors: similar, but slightly more conservative

$$\widehat{ATT} = \frac{1}{n} \sum_{i \in 1,2} n_i \cdot ATT_i$$

$$\widehat{se} = \sqrt{\frac{1}{n^2} \sum_{i \in 1,2} n_i^2 \cdot se_i^2}$$

## Health and Illness

**99. How would you describe your current health?**

Very good .....

Good .....

Satisfactory .....

Poor .....

Bad .....

**100. When you ascend stairs, i.e. go up several floors on foot:**

**Does your state of health affect you greatly, slightly or not at all?**

Greatly .....

Slightly .....

Not at all .....

**101. And what about having to cope with other tiring everyday tasks,**

**i.e. when one has to lift something heavy or when one requires agility:**

**Does your state of health affect you greatly, slightly or not at all?**

Greatly .....

Slightly .....

Not at all .....

# SF-12 Questionnaire

102. Please think about the last four weeks.

How often did it occur within this period of time, ...

Always    Often    Some-  
times    Almost    Never

- |   | Always                   | Often                    | Some-<br>times           | Almost                   | Never                    |
